19. ABSTRACT (Continue on reverse if necessary and identify by block number) Twenty diver-subjects were exposed to various levels of water temperature to assess how warm water affects cognition. Because cognitive performance is essential to operational performance and safety, determining cognitive effects of warm water exposure was desirable. The Automated Neuropsychological Assessment Metrics (ANAM) software was used before and after each exposure to provide near real-time assessment of diver neuropsychological status. Decrements in sustained attention, vigilance, memory, pattern recognition and basic problem solving were noted and appear to be functions of warm water exposure.

INTRODUCTION

This technical report partially addresses issues associated with Naval Sea Systems Command (NAVSEA) Task 99-005c and Annex A of Navy Experimental Diving Unit (NEDU) Test Protocol 99-22 (TP99-22).¹

Operational performance and safety are important in any challenging environment. Work in extremely warm water is an unexplored subject that this study addresses. The data gathered during this series of dives provide guidelines for early identification of potential changes in diver health and for investigations of divers' reports of subtle changes in their cognitive functioning.

The purposes of the study were to assess the neuropsychological safety of exposure to a warm water environment, to ensure proper documentation of the divers' neuropsychological state before and after warm water exposure, and to identify any residual effects from exposure to warm water.

METHODS

GENERAL

A sample of 20 diver subjects was exposed to various temperature and work modes to determine the effects of warm water on cognitive abilities. All pre-dive and post-dive assessments were made in the physiological laboratory at NEDU. All diving evolutions occurred in the NEDU test pool.

EXPERIMENTAL DESIGN AND ANALYSIS

Each subject participated in various phases of the study, but not at all work or temperature levels. For analytic purposes, the measurements were treated as independent observations, even though some subjects participated in multiple phases. The small sample sizes and phase memberships do not permit data to be analyzed as dependent observations across temperature and work modes.

The data were generated by the Automated Neuropsychological Assessment Metrics (ANAM) software.^{2,3} The variables considered were mean reaction time (MRT), the average response latency in milliseconds for the duration of each test; accuracy (acc), the percentage of correct responses for each test; and throughput (thruput), a measure of the number of correct responses made each minute and used as an index of mental efficiency.

The data were compiled using the Statview feature of ANAM³ and transferred to Microsoft® Excel for storage and manipulation. The data were then transferred to SPSS 10.0 for the analyses, which consisted of mixed Analyses of Variances (ANOVA) using the General Linear Model (GLM) Repeated Measure. Of the three factors, the first — the within-subject factor — consisted of two levels: the pre- and postdive assessment. The other two factors were

between-subject factors: temperature (five levels) and work mode (two levels). Tukey's post hoc test was used for all significant main effects of temperature.

EQUIPMENT AND INSTRUMENTATION

Only the equipment involved with ANAM will be discussed here. For more discussion of the other equipment used, please refer to NEDU TP99-22.¹

The equipment consisted of Micron Transport Trek II laptop computers (Micron PC, 900 East Karcher Road, Nampa, ID) with 366 Pentium processors, a standard mouse and the ANAM software.

The ANAM software is a standard clinical subset of the Office of the Military Performance Assessment Technology (OMPAT) Tester's Workbench (TWB).^{2,3} The ANAM was developed from selected elements of the Unified Tri-service Committee Performance Assessment Battery (UTCPAB)⁴ and the Walter Reed Performance Assessment Battery.⁵ ANAM's development and composition are discussed in detail elsewhere.^{2,3}

The tests in the ANAM battery were selected for assessing sustained concentration and attention; mental flexibility; spatial processing; cognitive processing efficiency; mood; arousal/fatigue level; and short-term, long-term, and working memory. Specifically, the ANAM battery that was used included the following subtests:³

- Demographics form
- Stanford Sleepiness Scale (measures alertness/fatigue level)
- Mood Scale 2-R (measures current mood level or state)
- Simple reaction time (measures basic psychomotor speed)
- Code substitution (measures visual scanning and learning through letter/symbol comparison)
- Code substitution with long and short delay (measures intermediate and delayed recall)
- Running memory continuous performance task (CPT) (measures working memory and executive functions)
- Mathematical processing task (measures computational speed and working memory)
- Matching to sample (measures delayed recall/longer-term memory)

Demographics, sleepiness and mood are not discussed here.

PROCEDURES

The study assessed responses of 20 subjects, 19 male and 1 female, each participating in various aspects of the study. Exposures to five water temperatures were investigated: 78, 94,

96.5, 99, and 101.5 °F. For all temperature levels except 78 degrees, investigations were made working and resting. In the work mode, each subject pedaled a bicycle either four hours or until he or she voluntarily aborted the trial. In rest mode, subjects were immersed for a total of eight hours or until they voluntarily aborted the trial. The specifics of the equipment used in the diving phase are covered in NEDU TP99-22.¹

Each subject took the neuropsychological assessment at least four times during a workup period to ensure a stable rate of performance before the study began. Then each subject took the assessment before each dive and within one hour of surfacing from the dive, provided that the subject did not abort the dive for displaying any of the medical criteria discussed in NEDU TP99-22.¹ If the subject did abort under these circumstances, he or she took the postdive portion of the assessment as soon as the other physiological measures and his or her condition allowed.

RESULTS

Appendix A lists means and standard errors of the mean (SEM) for each measure, while Appendix B shows the changes from baseline for each subject. For mean reaction time, performance decrements are increases from baseline, while for accuracy and throughput, decrements are decreases from baseline.

Appendix C lists the results of the repeated measures analysis of variance (ANOVA) for each variable. Significant effects of warm water diving are listed below:

Code substitution

Code substitution accuracy was lower after diving than before ($p = 0.018$), with no influence of water temperature or work mode. Code substitution MRT and throughput were not different after the dive from that before (no main effect).

Code substitution with short delay

Code substitution with short delay showed reduced accuracy ($p < 0.001$) and a marginally shortened MRT ($p = 0.05$) after dives, without influence of temperature or work mode.

Code substitution with long delay

No significant differences in MRT or throughput were caused by the dives. Diving reduced accuracy ($p < 0.001$) independently of temperature or work mode.

Simple reaction time

Diving did not affect simple reaction time measures.

Continuous performance task

Continuous performance accuracy and throughput both decreased after diving (accuracy $p = 0.001$, throughput $p = 0.03$). Neither accuracy nor throughput was affected by temperature or work mode.

Matching to sample

Matching to sample throughput decreased with diving ($p = 0.015$) without significant effects of temperature or work mode. MRT increased marginally with diving ($p = 0.051$), with a statistically significant temperature interaction ($p = 0.042$). The greatest reaction time increase was seen in 96.5 °F water.

Mathematical processing

No decrement in performance was associated with the dives.

DISCUSSION

Some changes in cognitive effects after diving were detected by ANAM. However, water temperature interacted significantly with diving only for matching to sample MRT. Unfortunately, due to our small sample size, our ability to discriminate other differences was impaired. The power of the tests is tabulated with the other statistics in Appendix C.

In the absence of a significant effect of the dives or of interaction with the dive exposure ("within factor 'A'"), effects ascribed to temperature or workload are caused by something other than the warm water diving. These effects have not been delineated.

Code substitution with short delay is a measure of short-term memory, and code substitution with long delay is a measure of long-term memory. They are generally correlated. The continuous performance task is a measure of vigilance or attention. Long and short-term memory functions and vigilance were reduced after the dives, but the decrements may have been caused by fatigue; temperature and work had no measurable influence.

Matching to sample is a test of pattern recognition and attention. Diving reduced accuracy, but water temperature did not affect the decrement. However, water temperature was related in some way to reaction time. The pattern is not clear because of the small sample sizes at higher water temperatures.

Mathematical processing was not indicative of diving effects. One possible reason is that it was the last test in the battery, administered after subjects were no longer motivated to perform. Possibly, single iterations of each subtest might produce better results.

CONCLUSIONS

Some cognitive changes were associated with warm water diving, but need to be further defined. Resolution of effects could be improved if larger sample sizes were available to increase statistical power. For this study comparisons to non-diving control groups were not possible because of other operational commitments, but they might also help differentiate between effects of fatigue and those of warm water diving.

The cognitive assessment of divers who must abort for medical or physiological reasons must be delayed until the diver's physical condition is stable. This prevents the detection of possibly important cognitive deficits that could accompany the physical distress. If one could use a single-run version of ANAM during the dive, one might measure cognitive function as the physical condition of the diver begins to deteriorate. Mid-point measurements could provide greater benefit, and single-run ANAM assessments require only a few minutes.

ANAM was unable to show a link between warm water exposure and neuropsychological risk. Pattern recognition speed may be reduced after warm water exposure, but this result must be regarded as preliminary because of the low number of subjects and the marginal probabilities. However, several divers had dramatic cognitive changes (confusion, hallucinations, etc...) immediately upon surfacing from the warm water dives. Tests of these divers were delayed until the divers were medically stable. Tests of all other divers were delayed at least 10 minutes and up to one hour after surfacing. These recovery periods may explain why ANAM was unable to detect the significant cognitive impairment seen immediately postdive at the warmer temperatures.

Finally, other methods should be used to assess factors of diver motivation and to assess decision making. In special warfare, the combatant must reach the operation area, make decisions based on a sound perception of available information, act on these decisions, and return safely. Preserving cognitive functioning is vital for completing missions and countermeasures must be developed to address any decrements in such capabilities, not only to ensure mission success, but also to ensure the safety of the individual.

Legend:

TEMP-Temperature of water
 WORK - Working rate
 work - Riding bicycle
 rest - No work
 premr - Mean reaction time baseline
 postmr - Mean reaction time postdive
 preacc - Accuracy baseline
 postacc - Accuracy postdive
 prethpt - Thruput score baseline
 postthpt - Thruput score postdive
 corr/min - Number of correct responses per minute (a purported measure of mental efficiency)

Legend:

TEMP-Temperature of water

WORK - Working rate

work - Riding bicycle

rest - No work

premr - Mean reaction time baseline

postmr - Mean reaction time postdive

preacc - Accuracy baseline

postacc - Accuracy postdive

prethpt - Thruput score baseline

postthpt - Thruput score postdive

corr/min - Number of correct responses per minute (a purported measure of mental efficiency)

Appendix B

Percentage from Baseline for Postdive Assessment

Legend: (Use for all charts)

Symbols represent the individual subjects

SMRT - Simple reaction time

MRT - Mean reaction time

ACC - Accuracy

Thruput - Throughput

CPT - Continuous performance task

Math - Mathematical processing

M2SP - Matching to sample

Codesub - Code substitution

Codesub MI - Code substitution short delay

Codesub MD - Code substitution long delay
